BACKGROUND OF THE INVENTION

Technical Field of the Invention

[0002] The present invention relates generally to processors and more particularly to an executable instruction that is capable of testing two values and skipping or executing the subsequent instruction based on the result of the test.

Background Information

[0003] Many types of electronic devices are battery operated and thus preferably consume as little power as possible. An example is a cellular telephone. Further, it may be desirable to implement various types of multimedia functionality in an electronic device such as a cell phone. Examples of multimedia functionality may include, without limitation, games, audio decoders, digital cameras, etc. It is thus desirable to implement such functionality in an electronic device in a way that, all else being equal, is fast, consumes as little power as possible and requires as little memory as possible. Improvements in this area are desirable.

BRIEF SUMMARY

[0004] As disclosed herein, a processor may execute an instruction that includes an immediate value and a reference to a register accessible to the processor. The instruction causes the processor to perform a test using the immediate value and the contents of the register referenced in the instruction. Based on the outcome of test, the subsequent instruction is executed or skipped. Further, the instruction includes at least one bit that specifies how the test is to be performed. The bit may specify that the immediate value is to be compared to the register value, or that the immediate value is used to mask the register value and the masked register value has one or more of its bits tested.

NOTATION AND NOMENCLATURE

[0005] Certain terms are used throughout the following description and claims to refer to particular system components. As one skilled in the art will appreciate, semiconductor companies may refer to a component by different names. This document does not intend to distinguish between components that differ in name but not function. In the following discussion and in the claims, the terms “including” and “comprising” are used in an open-ended fashion, and thus should be interpreted to mean “including, but not limited to...”. Also, the term “couple” or “couples” is intended to mean either an indirect or direct connection. Thus, if a first device couples to a second device, that connection may be through a direct connection, or through an indirect connection via other devices and connections. “Skipping” an instruction means that the instruction, which may have already been fetched by the processor, is not permitted to complete through the processor’s pipeline in favor of the instruction following the skipped instruction.

BRIEF DESCRIPTION OF THE DRAWINGS

[0006] For a more detailed description of the preferred embodiments of the present invention, reference will now be made to the accompanying drawings, wherein:

[0007] Figure 1 shows a diagram of a system in accordance with preferred embodiments of the invention and including a Java Stack Machine (“JSM”) and a Main Processor Unit (“MPU”);

[0008] Figure 2 illustrates an embodiment of the invention in the form of a wireless communication device;

[0009] Figure 3 shows a block diagram of the JSM of Figure 1 in accordance with preferred embodiments of the invention;

[0010] Figure 4 shows various registers used in the JSM of Figures 1 and 3; and

[0011] Figure 5 shows an exemplary format of a test and skip instruction in accordance with the preferred embodiment of the invention.

DETAILED DESCRIPTION

[0012] The following discussion is directed to various embodiments of the invention. Although one or more of these embodiments may be preferred, the embodiments disclosed should not be interpreted, or otherwise used, as limiting the scope of the disclosure, including the claims, unless otherwise specified. In addition, one skilled in the art will understand that the following description has broad application, and the discussion of any embodiment is meant only to be exemplary of that embodiment, and not intended to intimate that the scope of the disclosure, including the claims, is limited to that embodiment.

[0013] The subject matter disclosed herein is directed to a programmable electronic device such as a processor that executes various instructions including, without limitation, a “test with immediate and skip” instruction. The following describes the operation of a preferred embodiment of a processor on which the test with immediate and skip instruction may run. Other processor architectures and embodiments may be available or developed on which to run the instruction and thus this disclosure and the claims which follow are not limited to any particular type of processor. Details regarding the format and operation of the test with immediate and skip instruction follow the description of the processor.

[0014] The processor described herein is particularly suited for executing Java™ Bytecodes or comparable code. As is well known, Java is particularly suited for embedded applications. Java is a relatively “dense” language meaning that on average each instruction may perform a large number of functions compared to various other programming languages. The dense nature of Java

is of particular benefit for portable, battery-operated devices that preferably include as little memory as possible to save space and power. The reason, however, for executing Java code is not material to this disclosure or the claims which follow. The processor described herein may be used in a wide variety of electronic systems. By way of example and without limitation, the Java-executing processor described herein may be used in a portable, battery-operated cell phone. Further, the processor advantageously includes one or more features that permit the execution of the Java code to be accelerated.

[0015] Referring now to Figure 1, a system 100 is shown in accordance with a preferred embodiment of the invention. As shown, the system includes at least two processors 102 and 104. Processor 102 is referred to for purposes of this disclosure as a Java Stack Machine ("JSM") and processor 104 may be referred to as a Main Processor Unit ("MPU"). System 100 may also include memory 106 coupled to both the JSM 102 and MPU 104 and thus accessible by both processors. At least a portion of the memory 106 may be shared by both processors meaning that both processors may access the same shared memory locations. Further, if desired, a portion of the memory 106 may be designated as private to one processor or the other. System 100 also includes a Java Virtual Machine ("JVM") 108, compiler 110, and a display 114. The JSM 102 preferably includes an interface to one or more input/output ("I/O") devices such as a keypad to permit a user to control various aspects of the system 100. In addition, data streams may be received from the I/O space into the JSM 102 to be processed by the JSM 102. Other components (not specifically shown) may include, without limitation, a battery and an analog transceiver to permit wireless communications with other devices. As noted above, while system 100 may be representative of, or adapted to, a wide variety of electronic systems, an exemplary electronic system may comprise a battery-operated, mobile cell phone such as that is shown in Figure 2. As shown, a mobile

communications device includes an integrated keypad 412 and display 414. Two processors and other components may be included in electronics package 410 connected to keypad 410, display 414, and radio frequency (“RF”) circuitry 416 which may be connected to an antenna 418.

[0016] As is generally well known, Java code comprises a plurality of “bytecodes” 112. Bytecodes 112 may be provided to the JVM 108, compiled by compiler 110 and provided to the JSM 102 and/or MPU 104 for execution therein. In accordance with a preferred embodiment of the invention, the JSM 102 may execute at least some, and generally most, of the Java bytecodes. When appropriate, however, the JSM 102 may request the MPU 104 to execute one or more Java bytecodes not executed or executable by the JSM 102. In addition to executing Java bytecodes, the MPU 104 also may execute non-Java instructions. The MPU 104 also hosts an operating system (“O/S”) (not specifically shown), which performs various functions including system memory management, the system task management that schedules the JVM 108 and most or all other native tasks running on the system, management of the display 114, receiving input from input devices, etc. Without limitation, Java code may be used to perform any one of a variety of applications including multimedia, games or web based applications in the system 100, while non-Java code, which may comprise the O/S and other native applications, may still run on the system on the MPU 104.

[0017] The JVM 108 generally comprises a combination of software and hardware. The software may include the compiler 110 and the hardware may include the JSM 102. The JVM may include a class loader, bytecode verifier, garbage collector, and a bytecode interpreter loop to interpret the bytecodes that are not executed on the JSM processor 102.

[0018] In accordance with preferred embodiments of the invention, the JSM 102 may execute at least two instruction sets. One instruction set may comprise standard Java bytecodes. As is well-

known, Java is a stack-based programming language in which instructions generally target a stack. For example, an integer add (“IADD”) Java instruction pops two integers off the top of the stack, adds them together, and pushes the sum back on the stack. As will be explained in more detail below, the JSM 102 comprises a stack-based architecture with various features that accelerate the execution of stack-based Java code.

[0019] Another instruction set executed by the JSM 102 may include instructions other than standard Java instructions. In accordance with at least some embodiments of the invention, such other instruction set may include register-based and memory-based operations to be performed. This other instruction set generally complements the Java instruction set and, accordingly, may be referred to as a complementary instruction set architecture (“C-ISA”). By complementary, it is meant that the execution of some more complex Java bytecodes may be substituted by “micro-sequences” using C-ISA instructions that permit an address calculation process to “walk through” the JVM data structures. Further, such micro-sequences may also use bytecode instructions. Further, Java execution may be made more efficient and run faster by replacing some sequences of Bytecodes by preferably shorter and more efficient sequences of C-ISA instructions. Bytecodes also may be used within a C-ISA sequence. The two sets of instructions may be used in a complementary fashion to obtain satisfactory code density and efficiency. As such, the JSM 102 generally comprises a stack-based architecture for efficient and accelerated execution of Java bytecodes combined with a register-based architecture for executing register and memory based C-ISA instructions. Both architectures preferably are tightly combined and integrated through the C-ISA.

[0020] Figure 3 shows an exemplary block diagram of the JSM 102. As shown, the JSM includes a core 120 coupled to data storage 122 and instruction storage 130. The core may include one or

more components as shown. Such components preferably include a plurality of registers 140, three address generation units (“AGUs”) 142, 147, micro-translation lookaside buffers (micro-TLBs) 144, 156, a multi-entry micro-stack 146, an arithmetic logic unit (“ALU”) 148, a multiplier 150, decode logic 152, and instruction fetch logic 154. In general, operands may be retrieved from data storage 122 or from the micro-stack 146, processed by the ALU 148, while instructions may be fetched from instruction storage 130 by fetch logic 154 and decoded by decode logic 152. The address generation unit 142 may be used to calculate addresses based, at least in part on data contained in the registers 140. The AGUs 142 may calculate addresses for C-ISA instructions as will be described below. The AGUs 142 may support parallel data accesses for C-ISA instructions that perform array or other types of processing. AGU 147 couples to the micro-stack 146 and may manage overflow and underflow conditions in the micro-stack preferably in parallel. The micro-TLBs 144, 156 generally perform the function of a cache for the address translation and memory protection information bits that are preferably under the control of the operating system running on the MPU 104.

[0021] Referring now to Figure 4, the registers 140 may include 16 registers designated as R0-R15. Registers R0-R3, R5, R8-R11 and R13-R14 may be used as general purposes (“GP”) registers usable for any purpose by the programmer. Other registers, and some of the GP purpose registers, may be used for specific functions. For example, registers R4 and R12 may be used to store two program counters. Register R4 preferably is used to store the program counter (“PC”) and register R12 preferably is used to store a micro-program counter (“micro-PC”). In addition to use as a GP register, register R5 may be used to store the base address of a portion of memory in which Java local variables may be stored when used by the current Java method. The top of the micro-stack 146 is reflected in registers R6 and R7. The top of the micro-stack has a matching

address in external memory pointed to by register R6. The values contained in the micro-stack are the latest updated values, while their corresponding values in external memory may or may not be up to date. Register R7 provides the data value stored at the top of the micro-stack. Registers R8 and R9 may also be used to hold the address index 0 ("AI0") and address index 1 ("AI1"), as will be explained below. Register R14 may also be used to hold the indirect register index ("IRI") as will also be explained below. Register R15 may be used for status and control of the JSM 102. As an example, one status/control bit (called the "Micro-Sequence-Active" bit) may indicate if the JSM 102 is executing a "simple" instruction or a "complex" instruction through a "micro-sequence." This bit controls in particular, which program counter is used R4 (PC) or R12 (micro-PC) to fetch the next instruction. A "simple" bytecode instruction is generally one in which the JSM 102 may perform an immediate operation either in a single cycle (e.g., an "iadd" instruction) or in several cycles (e.g., "dup2_x2"). A "complex" bytecode instruction is one in which several memory accesses may be required to be made within the JVM data structures for various verifications (e.g., Null pointer, array boundaries). Because these data structures are generally JVM-dependent and thus may change from one JVM implementation to another, the software flexibility of the micro-sequence provides a mechanism for various JVM optimizations now known or later developed.

[0022] Referring again to Figure 3, as noted above, the JSM 102 is adapted to process and execute instructions from at least two instruction sets. One instruction set includes stack-based operations and the second instruction set includes register-based and memory-based operations. The stack-based instruction set may include Java bytecodes. Java bytecodes pop, unless empty, data from and push data onto the micro-stack 146. The micro-stack 146 preferably comprises the top n entries of a larger stack that is implemented in data storage 122. Although the value of n may be

vary in different embodiments, in accordance with at least some embodiments, the size n of the micro-stack may be the top eight entries in the larger, memory-based stack. The micro-stack 146 preferably comprises a plurality of gates in the core 120 of the JSM 102. By implementing the micro-stack 146 in gates (e.g., registers) in the core 120 of the processor 102, access to the data contained in the micro-stack 146 is generally very fast, although any particular access speed is not a limitation on this disclosure.

[0023] The second, register-based, memory-based instruction set may comprise the C-ISA instruction set introduced above. The C-ISA instruction set preferably is complementary to the Java bytecode instruction set in that the C-ISA instructions may be used to accelerate or otherwise enhance the execution of Java bytecodes. For example, the compiler 110 may scan a series of Java bytes codes 112 and replace one or more of such bytecodes with an optimized code segment mixing C-ISA and bytecodes and which is capable of more efficiently performing the function(s) performed by the initial group of Java bytecodes. In at least this way, Java execution may be accelerated by the JSM 102. The C-ISA instruction set includes a plurality of instructions including a “test with immediate and skip” instruction as mentioned above and explained below in detail.

[0024] Referring still to Figure 3, the ALU 148 adds, subtracts, and shifts data. The multiplier 150 may be used to multiply two values together in one or more cycles. The instruction fetch logic 154 generally fetches instructions from instruction storage 130. The instructions may be decoded by decode logic 152. Because the JSM 102 is adapted to process instructions from at least two instruction sets, the decode logic 152 generally comprises at least two modes of operation, one mode for each instruction set. As such, the decode logic unit 152 may include a Java mode in

which Java instructions may be decoded and a C-ISA mode in which C-ISA instructions may be decoded.

[0025] The data storage 122 generally comprises data cache (“D-cache”) 124 and data random access memory (“D-RAMset”) 126. Reference may be made to copending applications U.S. Serial nos. 09/591,537 filed June 9, 2000 (atty docket TI-29884), 09/591,656 filed June 9, 2000 (atty docket TI-29960), and 09/932,794 filed August 17, 2001 (atty docket TI-31351), all of which are incorporated herein by reference. The stack (excluding the micro-stack 146), arrays and non-critical data may be stored in the D-cache 124, while Java local variables, critical data and non-Java variables (e.g., C, C++) may be stored in D-RAM 126. The instruction storage 130 may comprise instruction RAM (“I-RAM”) 132 and instruction cache (“I-cache”) 134. The I-RAMset 132 may be used for “complex” micro-sequenced bytecodes or other micro-sequences or sequences of code, as will be described below. The I-cache 134 may be used to store other types of Java bytecode and mixed Java/CISA instructions.

[0026] As explained above, the C-ISA instruction set preferably permits register-based and memory-based operations. While not the only C-ISA instruction, as noted above one such instruction is the “test with immediate and skip” instruction. An exemplary embodiment of this instruction is depicted in Figure 5. The preferred embodiment of the test and skip with immediate instruction comprises an opcode 230, a reference 232 to a register (labeled generically as “Rd” in Figure 5), and an immediate value V 236. The immediate value may have any suitable format such as an eight-bit signed value.

[0027] The test with immediate and skip instruction 238 in Figure 5 generally operates in one of at least two modes depending on the state of at least one bit in register reference Rd 232. The Rd reference in Figure 5 preferably includes four bits (Rd[3:0]) with Rd[3] being the most significant

bit and occupying bit location 232a. The modes preferably are determined by the most significant bit Rd[3]. In some embodiments one mode is specified when Rd[3] is a logic “0”, while another mode is specified when Rd[3] is a “1”. In the former mode, Rd 232 references one of the registers from R0-R7, while in the latter mode, Rd references R8-R15. In other embodiments, a logic “1” for Rd [3] may specify the former mode and a logic “0” for Rd [3] may specify the latter mode, or a bit besides Rd [3] could be used to specify the mode.

[0028] In accordance with the preferred embodiment, as noted above when Rd [3] is a 0, the register Rd 232 encodes one of a first group of registers, preferably registers R0-R7 in Figure 4. If the immediate value V does not match the contents of the eight lower bits of the register referenced by Rd, then the instruction that follows the test and skip instruction 238 is “skipped.” Skipping the next instruction means that the subsequent instruction, which may have already been fetched by fetch logic 154, is not permitted to complete through the processor’s pipeline. Skipping the subsequent instruction may occur by replacing the instruction with a “no operation” (NOP) instruction which is permitted to complete but, by its nature, generally does nothing. Skipping the subsequent instruction may be performed other ways as well, such as by flushing the subsequent from the processor’s pipeline.

[0029] If, however, value V matches the contents of register Rd, then the subsequent instruction is executed, and thus not skipped. The combination of various logic including, without limitation, the decode logic 152 and/or fetch logic 154 may be used to perform the instruction replacement as described above. Further, the comparison of immediate value V with the contents of Rd may be performed by any suitable logic in the processor core 120 such as the ALU 148. The comparison preferably comprises a bit-by-bit comparison between V and the contents of Rd. If desired, a bit in the status register R15 may be written to reflect the result of the comparison. For example, this

status bit may be written as a “0” if V does not match the contents of Rd or as a “1” if there is a match.

[0030] The test with immediate and skip instruction avoids having to use a register to store the immediate value which may be helpful in cores having a limited number of registers. Further, the instruction described herein avoids having to load the immediate value from memory, thereby reducing the instruction count.

[0031] If Rd [3] is a logic 1, register reference Rd 232 encodes one of a second group of registers, preferably registers R8-R15. In this mode, the processor 102 generally examines the state of one or more bits, but not necessarily all bits, in register Rd. As such, the immediate value V is used to mask the contents of register Rd 232. This may be accomplished in the preferred embodiment by logically AND’ing register Rd with the immediate value V on a bit-by-bit basis. The mask (immediate value V) may comprise 0’s in the bit places that are not of interest, and 1’s in the bit places that are of interest. Once the contents of register Rd 232 are masked, the bits corresponding to the bit positions of the mask having a 1 are examined to determine whether they are a 0 or a 1. If the contents of register Rd, after masking, are not all 0’s, then the next instruction following the test and skip instruction 238 is skipped as described above. If, however, the masked register Rd is all 0’s, the subsequent instruction is executed and not skipped.

[0032] Targeting registers R8-R15 may be particularly appropriate for testing individual bits of the status register (e.g., the eight lower bits) and for jumping to a specific routine if one of those bits is set or continue to run another routine if not set. In the JSM architecture, some of these lower status bit may be used (set/cleared) by the MPU 104 to dynamically change the behavior of JSM 102. When one of these status bit is set to “1”, the micro-sequence executing complex bytecodes may behave differently than when the same status bit is set to “0”.

[0033] The format shown in Figure 5 is directed to a 16-bit instruction. Other embodiments of the test with immediate and skip instruction may include a different number of bits and/or a different number of bits for each of the fields shown in Figure 5. In some embodiments, the Rd[3] bit functionality may be replaced by the detection of a specific Rd field 232 value to target only a particular register (e.g., the status register R₁₅). Further, in some embodiments, the C bit 234 may be eliminated and two different opcodes 230 could be used to specify the different testing paradigms.

[0034] While the preferred embodiments of the present invention have been shown and described, modifications thereof can be made by one skilled in the art without departing from the spirit and teachings of the invention. The embodiments described herein are exemplary only, and are not intended to be limiting. Many variations and modifications of the invention disclosed herein are possible and are within the scope of the invention. Accordingly, the scope of protection is not limited by the description set out above. Each and every claim is incorporated into the specification as an embodiment of the present invention.
